User Input Block

User Input Block

Contents

- **1 User Input Block**
 - 1.1 Prompts tab
 - 1.2 Input Tab
 - 1.3 ASR Settings tab
 - 1.4 DTMF Settings tab
 - 1.5 Retry tab
 - 1.6 Results tab
 - 1.7 Milestone tab
 - 1.8 Example scenario
 - 1.9 Dynamic Grammars

You can use the **User Input** block in the **Self Service** phase to collect information from the user, such as an account number or credit-card information, and store it in a variable for processing. In the **Assisted Service** phase, you can use this block to gather more information from the user.

Optionally, you can specify whether retries are allowed if the input is not recognized, and whether to play a retry message, along with the original prompt message.

Tip

If the user enters invalid information or no input, then the value of the results variable is undefined. This must be considered before any later block can process the result. For example, a **Segmentation** block could determine whether the results variable stores a valid value and, based on the result, branches to different paths.

Prompts tab

Disable barge-in

Select this option to prevent callers from interrupting a prompt while it is still playing. For example, you might want a "Welcome" message to play all the way through before the caller can enter another command and skip to the next menu prompt.

If this option is not selected, barge-in is enabled, and the prompt can be interrupted by the caller.

Important

The selected barge-in setting applies irrespective of whether **global DTMF commands** are used or not.

Click **Add Prompt** to play prompts when the menu starts.

Set the timeout period, in seconds, to wait before assuming that no input was received from the caller. Refer to the **Retry** tab to specify which actions are taken if the timeout period is reached. If retries are not permitted and the timeout period is reached, the application moves onto the next block.

Properties - User Input

This block is used to ask a question and collect input from the user. It provides options for multiple attempts.

Prompts Input ASR Settings DTMF Settings Retry Results Milestone

Specify prompts to play to collect user input

☐ Disable barge-in

+ Add Prompt

Type	Var?	Value	Play as	Actions
TTS ▼	<input type="checkbox"/>	Your feedback is important to us.	text ▼	
TTS ▼	<input type="checkbox"/>	We would like to offer you a survey.	text ▼	
TTS ▼	<input type="checkbox"/>	Press 1 to take the survey.	text ▼	
TTS ▼	<input type="checkbox"/>	Press 2 to not take the survey.	text ▼	

Timeout - wait for s before assuming that no input was received.

Input Tab

Choose one of the following options:

Built-in Grammar

Select this option to use a built-in grammar. You can select from the following types:

- boolean
- currency
- date
- digits
- number
- phone
- time

If you select **digits**, you can also set the following options:

- **Minimum number of input digits** — Specify the minimum number of digits that the caller must enter.
- **Maximum number of input digits** — Specify the maximum number of digits that the caller can enter.

Next, specify the input mode for the grammar. You can select **DTMF**, **Speech**, or both. (If you select only **Speech** mode, **DTMF** grammars remain active but are not matched.)

Languages for built-in grammars can be managed using the *AppLanguageName* system variable (see [System variables](#)) or the [Change Language](#) block.

External Grammars

Select this option if you have created your own [speech grammar](#). Next, click **Add Grammar** to add one or more speech grammars to use with this block. Provide the following information:

- **Var?** - Enable this check box to indicate that the selected speech grammar will be determined by a variable.
- **Dynamic?** - Enable this check box to indicate that the selected speech grammar contains dynamic values that can change over time (for example, an employee directory). For more information, see [Dynamic Grammars](#).
- **Name** - Select the speech grammar name (or variable) that you want to add to this block.
- **Mode** - Specifies whether this speech grammar is for voice or DTMF.

ASR Settings tab

Use application-wide ASR settings

Enable this check box to use the default ASR (Automatic Speech Recognition) settings for your application. You can view or change these settings by clicking **Settings** in the Toolbar.

If you disable the **Use application-wide ASR settings** check box, you can set the following options for this block:

- **Confidence Level** - Specifies the speech recognition confidence level. If the caller's input is below this threshold, the input is determined as **No Match**. A value of 0.0 specifies that minimum confidence is needed for a match. A value of 1.0 specifies that maximum confidence is required before a match is determined.
- **Sensitivity** - Specifies the sensitivity level. A value of 1.0 specifies that speech recognition is highly sensitive to quiet input. A value of 0.0 specifies that speech recognition is least sensitive to noise.
- **Speed vs. Accuracy** - Specifies the balance between how fast the application responds to the input versus how accurate the response is interpreted. A value of 0.0 specifies that quick recognition is preferred. A value of 1.0 specifies that high accuracy is preferred.
- **Complete Timeout** - Specifies the required length of silence, in seconds, following user speech before the application determines a result (match, **No Match**, or **No Input**).
- **Incomplete Timeout** - Specifies the required length of silence, in seconds, following user speech before the application determines a result. This property is used in the following situations:

- If the speech prior to the silence does not match all active grammars, this property specifies how long to wait before the partial result is rejected as **No Match**.
- If the speech prior to the silence matches an active speech grammar, but it is still permissible to continue speaking and match the speech grammar. By contrast, **Complete Timeout** applies when the speech prior to the silence matches an active speech grammar and no further words are permissible.
- **Max Speech Timeout** - Specifies the maximum amount of time, in seconds, for which speech input is allowed before it is determined to be **No Match**.

Tip

If you change a setting and you later want to revert the setting to the default value, click **Global**.

DTMF Settings tab

Configure the following settings for DTMF input:

- **Input termination character** - Specify a termination character that the caller can enter to mark the end of the input string. Commonly, * or # are used as termination characters. If the caller does not enter a termination character, the application waits until the **Terminating Timeout** period has passed before processing the input.
Example: You set this value to #. The caller enters 1234#. The input is **1234** and # signals that no more characters will be entered.
- **Interdigit Timeout** is the amount of time, in seconds, that the application waits between digit inputs before assuming the end of the input string. If the user entered too few or too many digits, a retry is attempted. If retries are not allowed, the application moves on to the next block.
Example: You set this value to 3 and specify that the input can be between three and five digits. The caller enters 1234. The application waits **3** seconds before assuming a fifth digit will not be entered.
- **Terminating Timeout** is the amount of time, in seconds, that the application waits for the **Input Termination Character** before processing the input string. If the input is always a static length (for example, four characters), then you can set this value to 0 for the application to immediately process the input after the last digit is entered.
Example: If this value is **5** and the caller enters 1234, the application waits **5** seconds before processing the input.

Retry tab

Use application-wide retry

Enable this option to use the default retry settings for your application. You can view or change these settings by clicking **Settings** in the Toolbar.

Allow retries

If you disable the **Use application-wide retry** check box, you can enable **Allow retries** to specify retry rules for this block. You can set the following options:

- **Number of No Input retries allowed**
Select the number of retries to allow for callers whom do not provide input. For each retry, you can specify whether a prompt is played by clicking the corresponding section beneath this field. For example, if you allow two no-input retries and you want to play a prompt after the first retry, select the **No Input #1** line and add a prompt. Enable the **Play original menu prompt after this retry prompt** check box to repeat the menu prompts for the caller.
- **Number of No Match retries allowed**
Select the number of retries to allow for callers whom do not provide a match for a **Menu Block**. For each retry, you can specify whether a prompt is played by clicking the corresponding section beneath this field. For example, if you allow two no-input retries and you want to play a prompt after the first retry, select the **No Match #1** line and add a prompt. Enable the **Play original menu prompt after this retry prompt** check box to repeat the menu prompts for the caller.
- **After Final No Input**
Add the prompt to play after the maximum number of permitted No Input retries is reached. If this block is in the Self Service phase, you can also specify a target destination for the application to jump to, such as another block in the Self Service phase or to the Assisted Service or Finalize phase of the application.
- **After Final No Match**
Add the prompt to play after the maximum number of permitted No Match retries is reached. If this block is in the Self Service phase, you can also specify a target destination for the application to jump to, such as another block in the Self Service phase or to the Assisted Service or Finalize phase of the application.

Results tab

Specify the variables in which to store the results of the interaction, semantic interpretation, confidence score, and output result for speech recognition (such as the **Confidence Level** value).

Example

User Input Block

Properties - User Input

This block is used to ask a question and collect input from the user. It provides options for multiple attempts.

Prompts Input ASR Settings DTMF Settings Retry Results Milestone

Store output result (either DTMF entered digits, or the ASR utterance) in this variable (required)

varSurveyResponse

Store semantic interpretation in this variable

semInterpretation

Store confidence score in this variable

confScore

Store the output result details in this variable

semInterpretation

The format of the output result details variable will be an object with the contents:

Key	Type	Description
success	boolean	True if input was collected successfully.
interpretation	string	Interpreted value for the user input.
		Interpreted value for the user input.

Milestone tab

Specify a **milestone** for this block.

Example scenario

If you want to:

- Collect a single digit and allow for two retries. The caller can start collecting input only after the entire audio prompt has finished playing.
 - Disable barge-in:** Enabled
 - Minimum number of input digits:** 1
 - Maximum number of input digits:** 1
 - Allow retries:** Enabled
 - Number of No Input retries allowed:** 2
 - Number of No Match retries allowed:** 2

Dynamic Grammars

A dynamic grammar contains an array of values that automatically update in response to external input. Whereas traditional grammars are static and must be updated manually for each change, dynamic grammars are always current and do not require manual updates. This is useful for situations in which the grammar contents change frequently, such as employee or customer lists.

Consider the following example. You have created a voice application with a **User Input** block that allows the caller to contact specific employees in your company. You are using an external grammar that contains the names of all of your employees as valid inputs for this block. However, if an employee leaves the company or your company hires a new employee, the grammar is no longer current and must be updated. A dynamic grammar, however, can use an array of values from a variable and update itself based on external input. You do not need to manually update a dynamic grammar each time there is a change to the list.

There are two ways to create an array for use with dynamic grammars:

- Use an **HTTP REST** block.
- Use an **Assign Variables** block.

Using an **HTTP REST** Block

This method uses an **HTTP REST** block to fetch an array from a web service.

In this example, we are using a web service that returns the following JSON data:

```
{
  "success": true,
  "employees": ["John", "Julie", "Mark"]
}
```

Next, in the **Output Parameters** section of the **HTTP REST** block, we can assign **employees** to a User Variable that we previously created, called **varEmployees**.

Finally, in the **User Input** block, we can select **varEmployees** as a dynamic grammar. Each time the application runs, the **HTTP REST** block fetches the employee list and uses its contents as a dynamic grammar for the **User Input** block.

Using an **Assign Variables** Block

This method uses an **Assign Variables** block to push values to an array.

In this example, we have initialized a variable called **varEmployees** with a value of ' [] ' (an empty array).

Next, in the **Assign Variables** block, we use the expression `varEmployees.push(' John ')` to add an employee, **John**, to the employee list.

You can use multiple **Assign Variables** blocks to add items to the array.
